Dual Tone Multiple Frequency (DTMF)

National Semiconductor Application Note 521 Verne H. Wilson June 1989

Dual Tone Multiple Frequency (DTMF

The DTMF (Dual Tone Multiple Frequency) application is associated with digital telephony, and provides two selected output frequencies (one high band, one low band) for a duration of 100 ms. A benchmark subroutine has been written for the COP820C/840C microcontrollers, and is outlined in detail in this application note. This DTMF subroutine takes 110 bytes of COP820C/840C code, consisting of 78 bytes of program code and 32 bytes of ROM table. The timings in this DTMF subroutine are based on a 20 MHz COP820C/840C clock, giving an instruction cycle time of 1 μ s.

The matrix for selecting the high and low band frequencies associated with each key is shown in *Figure 1*. Each key is uniquely referenced by selecting one of the four low band frequencies associated with the matrix rows, coupled with selecting one of the four high band frequencies associated with the matrix columns. The low band frequencies are 697, 770, 852, and 941 Hz, while the high band frequencies are 1209, 1336, 1477, and 1633 Hz. The DTMF subroutine assumes that the key decoding is supplied as a low order hex digit in the accumulator. The COP820C/840C DTMF subroutine will then generate the selected high band and low band frequencies on port G output pins G3 and G2 respectively for a duration of 100 ms.

The COP820C/840C each contain only one timer. The problem is that three different times must be generated to satisfy the DTMF application. These three times are the periods of the two selected frequencies and the 100 ms duration period. Obviously the single timer can be used to generate any one (or possibly two) of the required times, with the program having to generate the other two (or one) times.

The solution to the DTMF problem lies in dividing the 100 ms time duration by the half periods (rounded to the nearest micro second) for each of the eight frequencies, and then examining the respective high band and low band quotients and remainders. The results of these divisions are detailed in Table I. The low band frequency quotients range from 139 to 188, while the high band quotients range from 241 to 326. The observation that only the low band quotients will each fit in a single byte dictates that the high band frequency be produced by the 16 bit (2 byte) COP820C/840C timer running in PWM (Pulse Width Modulation) Mode.

The solution then is to use the program to produce the selected low band frequency as well as keep track of the 100 ms duration. This is achieved by using three programmed register counters R0, R2, and R3, with a backup register R1 to reload the counter R0. These three counters represent the half period, the 100 ms quotient, and the 100 ms remainder associated with each of the four low band frequencies.

The theory of operation in producing the selected low band frequency starts with loading the three counters with values obtained from a ROM table. The half period for the selected frequency is counted out, after which the G2 output bit is toggled. During this half period countout, the quotient counter is decremented. This procedure is repeated until the quotient counter counts out, after which the program branches to the remainder loop. During the remainder loop. the remainder counter counts out to terminate the 100 ms. Following the remainder countout, the G2 and G3 bits are both reset, after which the DTMF subroutine is exited. Great care must be taken in time balancing the half period loop for the selected low band frequency. Furthermore, the toggling of the G2 output bit (achieved with either a set or reset bit instruction) must also be exactly time balanced to maintain the half period time integrity. Local stall loops (consisting of a DRSZ instruction followed by a JP jump back to the DRSZ for a two byte, six instruction cycle loop) are embedded in both the half period and remainder loops. Consequently, the ROM table parameters for the half period and remainder counters are approximately only one sixth of what otherwise might be expected. The program for the half period loop, along with the detailed time balancing of the loop for each of the low band frequencies, is shown in Figure 2.

The DTMF subroutine makes use of two 16 byte ROM tables. The first ROM table contains the translation table for the input hex digit into the core vector. The encoding of the hex digit along with the hex digit ROM translation table is shown in Table II. The row and column bits (RR, CC) representing the low band and high band frequencies respectively of the keyboard matrix shown in *Figure 1*, are encoded in

	Quotients, and Remainders								
	Frea	Freq. Hz Half Half Period Period 0.5P in μs		100 n	ns/0.5P				
	Hz			Quotient	Remainder

the two upper and two lower bits of the hex digit respectively. Consequently, the format for the hex digit bits is RRCC, so that the input byte in the accumulator will consist of 0000RRCC. The program changes this value into 1101RRCC before using it in setting up the address for the hex digit ROM translation table.

The core vectors from the hex digit ROM translation table consist of a format of XX00TT00, where the two T (Timer) bits select one of four high band frequencies, while the two X bits select one of four low band frequencies. The core vector is transformed into four different inputs for the second ROM table. This transformation of the core vector is shown in Table III. The core vector transformation produces a timer vector 1100TT00 (T), and three programmed counter the table content of the core vector the table content of table content of the table content of table

ter vectors for R1, R2, and R3. The formats for the three counter vectors are 1100XX11 (F), 1100XX10 (Q), and 1100XX01 (R) for R1, R2, and R3 respectively. These four vectors produced from the core vector are then used as inputs to the second ROM table. One of these four vectors (the T vector) is a function of the T bits from the core vector, while the other three vectors (F, Q, R) are a function of the X bits. This correlates to only one parameter being needed for the timer (representing the selected high band frequency), while three parameters are needed for the three counters (half period, 100 ms quotient, 100 ms remainder) associated with the low band frequency and 100 ms duration. The frequency parameter ROM translation table, accessed by the T, F, Q, and R vectors, is shown in Table IV.

In summary, the input hex digit selects one of 16 core vectors from the first ROM table. This core vector is then transformed into four other vectors (T, F, Q, R), which in turn are used to select four parameters from the second ROM table. These four parameters are used to load the timer, and the respective half period, quotient, and remainder counters. The first ROM table (representing the hex digit matrix table) is arbitrarily placed starting at ROM location 01D0, and has a reference setup with the ADD A, #0D0 instruction. The second ROM table (representing the frequency parameter table) must be placed starting at ROM location 01C0 (or 0xC0) in order to minimize program size, and has reference with the OR A, #0C3 instruction for the F vector.

The three parameters associated with the two X bits of the core vector require a multi-level table lookup capability with the LAID instruction. This is achieved with the following section of code in the DTMF subroutine:

	LD	B,#R1
	LD	X,#R4
	Х	A,[X]
LUP:	LD	A,[X]
	LAID	
	Х	A,[B+]
	DRSZ	R4
	IFBNE	#4
	JP	LUP

This program code loads the F frequency vector into R4, and then decrements the vector each time around the loop. This successive loop decrementation of the R4 vector changes the F vector into the Q vector, and then changes the Q vector into the R vector. This R4 vector is used to access the ROM table with the LAID instruction. The X pointer references the R4 vector, while the B pointer is incremented each time around the loop after it has been used to store away the three selected ROM table parameters (one per loop). These three parameters are stored in sequential RAM locations R1, R2, and R3. The IFBNE test instruction is used to skip out of the loop once the three selected ROM table parameters away.

The timer is initialized to a count of 15 so that the first timer underflow and toggling of the G3 output bit (with timer PWM mode and G3 toggle output selected) will occur at the same time as the first toggling of the G2 output bit. The half period counts for the high band frequencies range from 306 to 414, so these values minus 256 are stored in the timer section of the second ROM table. The selected value from this frequency ROM table is then stored in the lower half of the timer autoreload register, while a 1 is stored in the upper half. The timer is selected for PWM output mode and started with the instruction LD [B], #0B0 where the B pointer is selecting the CNTRL register at memory location 0EE.

The DTMF subroutine for the COP820C/840C uses 110 bytes of code, consisting of 78 bytes of program code and 32 bytes of ROM table. A program routine to sequentially call the DTMF subroutine for each of the 16 hex digit inputs is supplied with the listing for the DTMF subroutine.

LIFE SUPPORT POLICY

NATIONAL'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF NATIONAL SEMICONDUCTOR CORPORATION. As used herein:

- Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and whose failure to perform, when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury to the user.
- A critical component is any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
